

I'm not robot!

Android bold text in string. Bold in textview android.

To make text in your `TextView` Bold or Italic in Android Programming we need to make use of attribute `android:textAppearance`. It can have three values `normal`, `bold` and `Italic`. Android `TextView` Bold and Italic.png Example 1 : Bold Example 2 : Italic Example 3: Bold and Italic activity_main.xml Android `TextView` Bold and Italic.png More Posts related to Android, More Posts: [AndroidApps/ApplicationsMobile Development](#) This example demonstrates how do I make a specific text on `TextView` bold in android.
Step 1 – Create a new project in Android Studio, go to `File` = `New Project` and fill all required details to create a new project.
Step 2 – Add the following code to `res/layout/activity_main.xml`.
Let's try to run your application. I assume you have connected your actual Android Mobile device with your computer. To run the app from android studio, open one of your project's activity files and click `Run` icon from the toolbar. Select your mobile device as an option and then check your mobile device which will display your default screen –Click here to download the project code. Updated on 02-Aug-2019 08:24:31 Every Android device comes with a collection of standard fonts: Droid Sans, Droid Sans Mono and Droid Serif. They were designed to be optimal for mobile displays, so these are the three fonts you will be working with most of the time and they can be styled using a handful of XML attributes. You might, however, see the need to use custom fonts for special purposes. This guide will take a look at the `TextView` and discuss common properties associated with this view as well as how to setup custom typefaces. Text Attributes Typeface As stated in the overview, there are three different default typefaces which are known as the Droid family of fonts: sans, monospace and serif. You can specify any one of them as the value for the `android:typeface` attribute in the XML: Here's how they look: In addition to the above, there is another attribute value named "normal" which defaults to the sans typeface. Text Style The `android:textStyle` attribute can be used to put emphasis on the text. The possible values are: `normal`, `bold`, `italic`. You can also specify `bold|italic`. A sampling of styles can be seen below: Text Size `android:textSize` specifies the font size. Its value must consist of two parts: a floating-point number followed by a unit. It is generally a good practice to use the `sp` unit so the size can scale depending on user settings. A sampling of styles can be seen below: Too many type sizes and styles at once can wreck any layout. The basic set of styles are based on a typographic scale of 12, 14, 16, 20, and 34. Refer to this typography styles guide for more details. Text Truncation There are a few ways to truncate text within a `TextView`. First, to restrict the total number of lines of text we can use `android:maxLines` and `android:minLines`. In addition, we can use `android:ellipsize` to begin truncating text. Following values are available for `ellipsize`: `start` for `...bccc`, `end` for `aaab...`, `middle` for `aa...cc`, and `marquee` for `aaabbbccc` sliding from left to right. Example: There is a known issue with `ellipsize` and multi-line text, see this `MultipleLineEllipsizeTextView` library for an alternative. Text Color The `android:textColor` and `android:textColorLink` attribute values are hexadecimal RGB values with an optional alpha channel, similar to what's found in CSS. The `android:textColorLink` attribute controls the highlighting for hyperlinks embedded within the `TextView`. This results in: We can edit the color at runtime with: // based on hex value `textView.setTextColor(Color.parseColor("#000000"))`; // based on a color resource file `textView.setTextColor(ContextCompat.getColor(context, R.color.your_color))`; // based on preset colors `textView.setTextColor(Color.RED)`; // based on hex value `textView.setTextColor(Color.parseColor("#000000"))`; // based on a color resource file `textView.setTextColor(ContextCompat.getColor(this, R.color.your_color))`; // based on preset colors `textView.setTextColor(Color.RED)` Text Shadow You can use three different attributes to customize the appearance of your text shadow: `android:shadowColor` - Shadow color in the same format as `textColor`. `android:shadowRadius` - Radius of the shadow specified as a floating point number. `android:shadowDx` - The shadow's horizontal offset specified as a floating point number. `android:shadowDy` - The shadow's vertical offset specified as a floating point number. The floating point numbers don't have a specific unit - they are merely arbitrary factors. This results in: Various Text Properties There are many other text properties including `android:lineSpacingMultiplier`, `android:letterSpacing`, `android:textAllCaps`, `android:includeFontPadding` and many others: `android:includeFontPadding` removes the extra padding around large fonts. `android:lineSpacingMultiplier` governs the spacing between lines with a default of "1". Inserting HTML Formatting `TextView` natively supports HTML by translating HTML tags to spannable sections within the view. To apply basic HTML formatting to text, add text to the `TextView` with: `TextView view = findViewById(R.id.sampleText); String formattedText = "This is a test of html" // or getString(R.string.htmlFormattedText); view.setText(HtmlCompat.fromHtml(formattedText, HtmlCompat.FROM_HTML_MODE_LEGACY));` val view: TextView = findViewById(R.id.sampleText) val formattedText = "This is a test of html" // or getString(R.string.htmlFormattedText) view.text = HtmlCompat.fromHtml(formattedText, HtmlCompat.FROM_HTML_MODE_LEGACY) You can read more about the html modes here. This results in: Note that all tags are not supported. See this article for a more detailed look at supported tags and usages. Setting Font Colors For setting font colors, we can use the tag as shown: `HtmlCompat.fromHtml("Nice! This text has a color. This doesn't", HtmlCompat.FROM_HTML_MODE_LEGACY);` `HtmlCompat.fromHtml("Nice! This text has a color. This doesn't", HtmlCompat.FROM_HTML_MODE_LEGACY)` And you should be all set. Storing Long HTML Strings If you want to store your HTML text within `res/values/strings.xml` you have to use `CDATA` to escape such as: let us know if you have feedback on this or if you would like to log in with another identity service. Thanks!]> and access the content with `getString(R.string.htmlFormattedText)` to load this within the `TextView`. For more advanced cases, you can also check out the `html-textview` library which adds support for almost any HTML tag within this third-party `TextView`. Autolinking URLs `TextView` has native support for automatically locating URLs within their text content and making them clickable links which can be opened in the browser. To do this, enable the `android:autolink` property: This results in: Issues with `ListView` One known issue when using `android:autoLink` or the `Linkify` class is that it may break the ability to respond to events on the `ListView` through `setOnItemClickListener`. Check out this solution which extends `TextView` in order to modify the `onTouchEvent` to correctly propagate the click. You basically need to create a `LinkifiedTextView` and use this special `View` in place of any of your `TextView`'s that need auto-link detection. In addition, review these alternate solutions which may be effective as well: Displaying Images within a `TextView` A `TextView` is actually surprisingly powerful and actually supports having images displayed as a part of its content area. Any images stored in the "drawable" folders can actually be embedded within a `TextView` at several key locations in relation to the text using the `android:drawableRight` and the `android:drawablePadding` property. For example: Adding custom fonts We can actually use any custom font that we'd like within our applications. Check out `fontsquirl` for an easy source of free fonts. For example, we can download `Chantelli Antiqua` as an example. Fonts are stored in the "assets" folder. In Android Studio, `File` > `New` > `folder` > `Assets Folder`. Now download any font and place the `TTF` file in the `assets/fonts` directory: We're going to use a basic layout file with a `TextView`, marked with an id of "custom_font" so we can access it in our code.
